Building the Magnésie APK with GitHub Actions

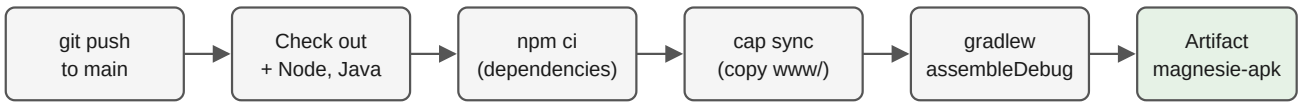

Applies to repository TinoCoda/magnesie · workflow file `.github/workflows/android.yml` · Created by Tino · 03.10.2026

1. What the workflow does

The workflow “Compiler l'APK Android” runs on a GitHub server (Ubuntu) and turns the code into an installable Android APK. Nothing needs to be installed on your computer.

Step in the file	Command / action	Purpose
Check out code	`actions/checkout@v4`	Downloads the repository onto the server.
Node 22 + Java 21	`setup-node`, `setup-java`	Installs the tools Capacitor (Node) and Gradle (Java, Temurin) need; npm downloads are cached.
Install dependencies	`npm ci`	Installs the exact versions from `package-lock.json`.
Copy web app	`npx cap sync android`	Copies the `www/` folder into the Android project.
Build APK	`./gradlew assembleDebug`	Compiles the Android project (inside `android/`).
Upload result	`upload-artifact@v4`	Stores `app-debug.apk` as the downloadable artifact **magnesie-apk**.

2. Flow

runs on GitHub's server · about 5–10 minutes

Green box = what you download.

3. How to use it

1. **Start a build automatically:** push to `main` (or `master`). Every push triggers a run.
2. **Start a build by hand:** on GitHub open the **Actions** tab → “Compiler l'APK Android” → **Run workflow** (enabled by `workflow_dispatch`).
3. **Follow the run:** click the run in the list. Yellow = running, green = success, red = failed. Click a step to read its log; a red step shows the error.
4. **Download the APK:** open the finished run, scroll to **Artifacts** and download **magnesie-apk**. It is a zip containing `app-debug.apk`.
5. **Install on the phone:** copy the APK to the phone and open it. Android asks once to allow “Install unknown apps” for the browser or file manager you used.
6. **Update the app:** edit the code (e.g. `www/app.js`), commit, push to `main`, then repeat steps 3–5.

> **Good to know:** this is a *debug* APK, fine for personal use but not signed for the Play Store. Run #1 on 03.10.2026 completed successfully.
